Abstract
A 67-year-old male with Ebstein's anomaly and a dual-chamber pacemaker due to sick sinus syndrome was admitted to our hospital with cardiogenic shock. Echocardiography revealed severe functional mitral valve regurgitation with preserved ejection fraction. He was referred for percutaneous mitral valve repair (PMVR) for refractory shock in the setting of prohibitive surgical risk. Invasive hemodynamics obtained during PMVR revealed worsening mitral regurgitation due to septal dyssynchrony induced by the patient's permanent pacing. He underwent successful PMVR with subsequent clinical recovery. Dyssynchrony from right ventricular apical pacing may exacerbate mitral regurgitation and heart failure. PMVR with MitraClip may be a safe and effective therapeutic option in patients with refractory cardiogenic shock and severe mitral regurgitation.

Introduction
Percutaneous edge-to-edge mitral valve repair (PMVR) using the MitraClip (Abbott, Menlo Park, CA, USA) system is a novel method of reducing severe symptomatic degenerative mitral valve regurgitation (MR) in high-risk or inoperable patients. Although randomized trials for its use in functional MR and end-stage heart failure are currently underway, there are a few reported cases of its use as a rescue therapy in critically ill patients with refractory cardiogenic shock [1, 2]. Here, we present a case of cardiogenic shock in a patient with Ebstein's anomaly secondary to severe functional MR who underwent successful PMVR.

Case Presentation
A 67-year-old male with Ebstein's anomaly, history of bioprosthetic tricuspid valve replacement for tricuspid regurgitation, and dual-chamber pacemaker due to sick sinus syndrome presented to the emergency department with progressive dyspnea on exertion, abdominal distension, a 7-kg weight gain, and severe orthopnea. In the preceding 5 years, he had re-
required multiple hospitalizations for dyspnea, weight gain, and abdominal distension despite escalating doses of diuretics.

On physical examination, he was severely dyspneic with an oxygen saturation of 95% on non-invasive bi-level positive pressure ventilation. His blood pressure was 96/67 mmHg with an atrioventricular paced heart rate of 80 beats per minute. His physical examination was notable for significant jugular venous distension, a grade II/VI holosystolic murmur heard loudest at the apex, bibasilar crackles, abdominal distension, and 1+ bilateral lower extremity edema. Serum brain natriuretic peptide was elevated at 364 pg/mL, and chest radiography showed enlargement of the cardiac silhouette, vascular congestion, pulmonary edema, and bilateral pleural effusions (Figure 1A).

Transthoracic and transesophageal echocardiography revealed severe MR, severe biatrial enlargement, and preserved left ventricular ejection fraction with left ventricular end-diastolic and end-systolic dimensions of 52 mm and 40 mm, respectively (Figure 2A and 2B, Video 1 and 2). Tenting of the mitral leaflets with poor coaptation of anterior and posterior leaflets was noted, consistent with functional MR. The bioprosthetic tricuspid valve appeared to function normally. Within 24 h of admission, he quickly progressed to cardiogenic shock requiring dobutamine and dopamine, and progressive anuric renal failure requiring continuous renal replacement therapy. He was evaluated for PMVR with V-Clip given prohibitive surgical risk with 30-day Society of Thoracic Surgeons predictive operative mortality risk scores of 43% and 36% for mitral valve replacement and repair, respectively.

Table 1. Invasive hemodynamics immediately before and after percutaneous mitral valve repair. Note all hemodynamics were measured on the same dosages of dopamine, dobutamine, and epinephrine.

as the patient was predominantly atrioventricular (AV) paced, a drop in V waves and concurrent rise in aortic waveforms was observed when the patient had native AV conduction. In comparison, resumption of

Figure 3. Invasive cardiac hemodynamics measuring simultaneous aortic (purple) and left atrial (yellow) waveforms before mitral valve repair. When the patient was in a ventricular paced rhythm, increased left atrial pressures with a mean of 30 mmHg with prominent V waves of up to 75 mmHg were noted. Simultaneous central aortic pressures decreased with ventricular pacing (mean 58 mmHg). Native ventricular conduction was associated with decreased left atrial pressures (mean 20 mmHg) with smaller V waves and enhanced arterial pressures (mean 68 mmHg). Ao = aortic pressures; LA = left atrial pressure.

Figure 4. Intraprocedural fluoroscopy, anteroposterior view, during MitraClip procedure. Panel A. Fluoroscopy performed after trans-septal puncture. Balloon dilation (circle) of the interatrial septum was performed to allow for passage of the MitraClip delivery catheter. Panel B. Fluoroscopy visualizing the placement of three MitraClips (arrows).

Intraoperative pre-repair hemodynamics revealed two distinct left atrial and arterial waveforms depending on the patient’s cardiac rhythm, illustrating its electromechanical influence on MR (Figure 3). Where-
Postoperatively, the patient was rapidly weaned off vasopressor support with recovery of renal function (Figure 1B). He was discharged 10 days after the procedure, with plans for pacemaker upgrade to cardiac resynchronization therapy. One month post-procedure, he was doing well, with New York Heart Association class II symptoms and maintenance of a stable weight on an oral diuretic regimen with brain natriuretic peptide of 126 pg/mL. Follow-up echocardiography confirmed no significant changes, with stable mild residual MR.

Discussion

Cardiac pacing is an established and effective treatment for a variety of bradyarrhythmias. Although the
Clinical scenarios ranging from acute severe MR immediately following pacemaker implantation to slow progression of MR in the setting of chronic right ventricular apical pacing [4-6].

The mechanism of MR with RV pacing is derived from intraventricular dyssynchrony. Pacing from the right ventricular apex induces an iatrogenic form of left bundle branch block as depolarization spreads from the apex to the base, as demonstrated by the patient’s electrocardiograms before and after du-

right ventricular apex is the standard pacing site for dual-chamber pacemakers, several studies report detrimental effects of electrical dyssynchrony from RV pacing, including exacerbation of valvular dysfunction and heart failure [3, 4].

In this case, invasive hemodynamics obtained during PMVR demonstrated worsening of functional MR from septal dyssynchrony induced by RV apical pacing. The association between MR and right ventricular apical pacing has been described in many clinical scenarios ranging from acute severe MR immediately following pacemaker implantation to slow progression of MR in the setting of chronic right ventricular apical pacing [4-6].

Figure 6. Twelve-lead electrocardiograms. Panel A. Electrocardiogram prior to pacemaker placement, demonstrating atrial fibrillation with an incomplete right bundle branch block pattern, with normal axis and nonspecific ST-T segment abnormalities seen inferolaterally. Panel B. Electrocardiogram after dual-chamber pacemaker placement, demonstrating an atrioventricular paced rhythm and a paced ventricular morphology with an indeterminate axis and atypical left bundle branch morphology (no broad R waves noted in lateral leads). Pseudofusion (thick arrow) was intermittently noted, revealing the patient’s native QRS morphology and fusion (thin arrow).

al-chamber pacemaker placement (Figure 6). This abnormal left ventricular activation sequence causes delayed reduction of both the mitral annular size and regurgitant orifice size, leading to abnormal leaflet coaptation and enhanced MR [7].

Moreover, a hallmark of Ebstein’s anomaly is dysynchrony of the basal septum at the attachment site of the septal leaflet [8]. Although the patient had previously undergone surgical tricuspid valve replacement, residual septal dyskinesis may have also further contributed to worsened MR.

This case highlights the hemodynamic effects of right ventricular pacing in MR and demonstrates the potential utility of the MitraClip system as a feasible and effective salvage therapy option in refractory cardiogenic shock. Further experience and research is needed to clarify which patients can be hemodynamically significantly affected by right ventricular pacing.
